The assay is versatile in that any number of test sequences CC can be tested by placing the test sequence adjacent to a defined protein CC binding screening sequence. Binding of mols. to these test sequences CC changes the binding characteristics of the protein mol. to its cognate CC binding sequence. When such a mol. binds the test sequence, the CC could be concentration of free DNA probe. One application of this method is to eucaryotic general transcription factors (e.g. TPIID), where the target region is typically selected from DNA sequences adjacent to the CC target region is typically selected from DNA sequences adjacent to the CC binding site for the eucaryotic transcription factor. Numerous exemplary CC test sequences are given: the sequences in AAQ69251-731 and AAQ69850 CC correspond to promoter targets (typically, TATA box-contg. sites) for human genes and the sequences in AAQ69732-849 correspond to promoter CC targets for viral genes. The test sequences may also be randomly CC generated. DNA:protein interaction may be used for screening purposes, ce.g. the Herpes Simplex Virus (HSV) origin of replication and UL9 (see CAAQ69851-52, AAQ69865 and AAQ69891). (Updated on 25-MAR-2003 to correct CC DNA(69851-52, AAQ69865 and AAQ69891). (Updated on 25-MAR-2003 to correct
                                                                                                                                                                                                                                 RESULT 2
                                                                                                                                                                                                                                                                                    밁

                                                                                                                                                                                                              the binding characteristics of a DNA-binding protein to duplex DNA comprises contacting the duplex DNA with a small molecule which binds sequence-specifically to a target region, where, when the small molecule is bound to the target region, it is adjacent to, but not overlapping by more than 4 bp, a binding site for a DNA-binding protein. The small components of the DNA binding protein, pref. TFIID, to its binding site on the duplex DNA. The binding of the small molecule may inhibit or enhance the binding of the DNA-binding protein to its binding site. The compounds isolated compounds in the binding of the small molecule may inhibit or enhance the binding of the DNA-binding protein to its binding site. The compounds isolated compounds in the binding site of a sequence, e.g. cancer, or inherited genetic disorders etc. The method is suitable for conserving large biological or chemical libraries and allows determination of sequence-specific and relative affinities of known DNA-binding agents for different DNA sequences. The deasign of these duplex DNA's allows a single DNA:portein interaction to be used for screening sequence-specific, or preferential, DNA binding proteins that recognise almost any possible sequence (see also AAT49539-74). The method comprises:

(i) adding a test molecule and a DNA-binding protein to a mixture of diplex DNA test oligonucleotides, each of the test oligonucleotides
                                                                      DNA binding molecule screening; inhibition of transcription; human immunodeficiency virus; HIV; parasite; cancer; cardiova respiratory; gastrointestinal; endocrine; metabolic; rheumati immunological; haematological; neurological;

                                                                                                                                                                                                                                                                                                                                                              ş
                                                                                                                                                                                                                                                                                                                                                                                                                                                                              The invention relates to a method of decreasing transcriptional activity CC in a duplex deoxyribonucleic acid (DNA) template (T1) comprising CC contacting (T1) with a binding agent comprising at least one small duplex DNA-binding molecule (T2) coupled to at least one small duplex comparison of the comprising region of target sequence (TS). The method is useful for inhibiting region of target cange of disease-related genes for treating infections (by viruses, concluding human immunodeficiency virus, bacteria, fungi, protozoa and comparasites), cancer, cardiovascular, respiratory, gastrointestinal, concor, cardiovascular, respiratory, gastrointestinal, concording/metabolic, rheumatic/immunological, haematological, musculocated endocrine/metabolic, rheumatic/immunological, ophthalmological, musculocated endocrine/metabolic, rangeription of pathological genes without affecting transcription of transcription of pathological genes without transcription factor, and can be applied to regulation of any gene. CC Lakea242-ABK82155 represent DNA binding molecule test sequences used in the method of the invention
                                                                                                                                                                                                                                                                                                                                                                                             Matches

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  gene, where the gene corresponds to any of 8143 oligonucleotides (ABZ00010-ABZ08152) each having 50 base pairs (bp). The system is useful for leukocyte expression profiling. It is particularly useful for disgnosing a disease, monitoring (rate of) progression of a disease, predicting therapeutic outcome, determining prognosis for a patient, predicting disease complications in an individual or monitoring response to treatment in an individual. The diseases include cardiac allograft rejection, kidney allograft rejection, liver allograft rejection, atheroselerosis, congestive heart failure, systemic lupus erythematosus, rheumatoid arthritis, osteoarthritis or cytomegalovirus infection
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              New system for leukocyte expression profiling, diagnosing a disease, or monitoring (the rate of) progression of a disease, e.g. atherosclerosis or congestive heart failure, comprises diagnostic oligonucleotides.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              The invention relates to a system for detecting gene expression, which comprises one or two isolated DNA molecules that detect expression of a gene, where the gene corresponds to any of 8143 oligonucleotides (ABZ00010-ABZ08152) each having 50 base pairs (bp). The system is useful for leukocyte expression profiling. It is particularly useful for diagnosing a disease, monitoring (rate of) progression of a disease, predicting therapeutic outcome, determining prognosis for a patient, predicting disease complications in an individual or monitoring response to treatment in an individual. The diseases include cardiac allograft rejection, kidney allograft rejection, liver allograft rejection, atherosclerosis, congestive heart failure, systemic lupus erythematosus, because of the content of the cont

This invention relates to novel methods for diagnosing and matter autoimmune and chronic inflammatory diseases. Specifically,

monitoring, it refers

ö

or

```
the identification of genes that have a clinical utility as diagnostic tools for the management of, in particular, patients with systemic lupus erythematosis (SLE) or rheumatoid arthritis (RA). Accordingly, the present invention describes a method for determining the levels of multiple differentially expressed genes of a patient, in a concerted manner, in order to achieve an improved diagnostic assay with sensitivity and specificity for the disease in question. As such, these genes are useful for the diagnosis of various other inflammatory disorders including cholecystitis, Sjogren's disease, CREST syndrome, scleroderma, ankylosing spondylitis, ulcerative colitis, primary sclerosing cholangitis, appendicitis, diverticulitis, and primary biliary sclerosis. This oligonucleotide is a human DNA probe used to monitor the expression level of the differentially expressed diagnostic genes of the invention.

Screening for sequence-directed DNA-binding molecules comprises adding test molecule to a test system composed of a DNA-binding protein and a duplex DNA test oligonucleotide having adjacent screening and test

Claim 2; QES ID NO 214; 283pp; English

The invention describes a method for screening for molecules capable obinding to a selected test sequence in a duplex DNA. The above method comprises: constructing a duplex DNA test oligonucleotide having a screening sequence adjacent to a selected test sequence, where a DNA-binding protein is effective to bind to the screening sequence with a binding affinity that is substantially independent of such test sequence but where DNA protein binding to the screening sequence is sensitive to sensitive to ဓ္
